Dobkin's Results

The Delaunay triangulation of a set of points in the plane is a spanner with spanning ratio $c \leq ((1+\sqrt{5})/2)\pi \approx 5.08$. This was proven in the paper "Delaunay Graphs Are Almost as Good as Complete Graphs" by Dobkin, Friedman, and Supowit [1] [2].

Introduction

Let S be a set of points in the plane and $DT(S)$ be the edges of the Delaunay triangulation of S. Let a path along the Delaunay edges be a *direct DT path*.

One-Sided Path: The Easy Case

If all edges along the direct DT path between points $a, b \in S$ are either all above or all below the line connecting a, b, we say that this is a one-sided path.

Lemma 1. *Points along a direct DT path are monotonic in x.*

Lemma 2. *All points along the direct DT path from a to b are contained within or on the boundary of the circle with a and b diametrically opposed.*

Lemma 3. *The boundary of a connected union of circles has boundary at most $\pi \cdot (x_r - x_l)$ where x_r and x_l are the extreme x coordinates of any of the circles.*

From these lemmas, it follows the direct DT path is at most $\pi/2$ times as long as the euclidean distance between the endpoints.

The Harder Case
